AI FAQ Assistant API

PHASE 4: TESTING AND OUTPUT

Objective

Check that the API works correctly under normal and invalid conditions.

Test Cases

Valid question returns an answer; empty question returns a validation error; malformed JSON returns an error; unavailable AI service is handled gracefully; missing configuration produces a safe server error.

Testing Tools

Postman, Thunder Client, or curl may be used to send HTTP requests and inspect responses.

Output Evidence

Insert actual screenshots of successful requests, JSON responses, and error cases from the running project.

Conclusion

Testing helps verify request handling, AI integration, and error responses. Record actual test results after running the project.
